Executive Summary Report on scottyab/rootbeer

From this scatterplot, I can deem that Scott Alexander-Bown was the most active throughout the active lifetime of the repository. The active lifetime was close to 350 weeks at the time of writing this report. Scott Alexander-Bown was involved in various files throughout the project, potentially signifying a leading role within the project, especially considering they were involved in the project since week 0. Matthew Rollings is in a similar position as they are involved in many files throughout the project's lifetime and are constantly active throughout, though not as much as Scott.

Then, based on the file commits stored in a csv file, Alexander-Bown and Rollings were working on files like CheckForRootWorker.kt, CheckRootTask.java, MainActivity.kt and MainActivity.java, possibly showing they were working on the main structure of the entire project.

From there, a new author in grubeli made the most recent project, though they aren't seen earlier in the project, meaning they are a new member. Mohammed Ezzat was involved earlier on within the first year of the project, but they have no commits from there, showing they may have left the project.

Throughout this lab, there were many git commands that helped. Git add, git commit, and git push, helped me keep updated code on the remote repository. Git pull helped me stay updated with my teammates' work. Git branch and git checkout helped me generate branches to organize my code.
